Alerting Abstract TP A

A technique is disclosed for securing a computer system using logins from entry by persons not forming part of the computer system by eliminating the luxury of eliminating wrong passwords with every access attempt. The present technique allows a computer administrator to arbitrarily set penalty standards when access to the system is tried. The system looks at both the prior and present password to see if it was presented correctly or incorrectly, and makes an arbitrary decision as to whether or not to permit access to the system. For example, if both the prior and present password were presented correctly, then the system might effectively flip a coin to grant access or not (50% change of entry). If such access was not granted, then a second correct attempt would increase the odds to, for example, a 100% chance of entry. However, each incorrect password presentation would decrease the odds of gaining entry by some arbitrary amount, requiring additional correct entries thereafter to increase the odds of gaining entry. The technique could also (1) look at the alphanumeric typed for the password and see how close it is to the correct one to determine if it might just be a typing error and then either decrease the odds only slightly or not at all, and/or (2) look at past usage of the computer by the user (just editing, just programming) to see if patterns have changed indicating that a hacker might have gained access to alert system personnel

Alerting Abstract US A1

NOVELTY - A **lockout** count is variably incremented if the presented password fails to exactly match the stored password, and access to the item is **locked** out if the **lockout** count exceeds a predetermined value. The **lockout** count is incremented depending on how **closely** the presented **password** matches the stored password.

DESCRIPTION - An **INDEPENDENT CLAIM** is also included for recorded medium storing program for authorizing access to an item.

USE - For authorizing access to item e.g. protected computer resource.

ADVANTAGE - Identifies invalid logon attempts which are likely to be due to human error and weights these with lesser magnitude than those logon failures more likely to stem from hostile intrusion, thus minimizing inconvenience and inefficiency due to innocent human error without sacrificing security.

DESCRIPTION OF DRAWINGS - The figure shows a flowchart of steps involved in **locking** out user identifications.
